

Part 2: Autopsy report

The medical examiner concluded that each of the victims had died of hypoxia. **Hypoxia** means that the person suffered from a lack of oxygen, or they were suffocated. The reason for the hypoxia is not always clear at the first examination.

The medical examiner also showed the tissue samples from the heart, lungs, and liver showed massive cell death. On further investigation, it was shown that the tissues had major mitochondrial damage.

Even though the victims died of hypoxia, their level of oxygen in their blood was approximately 110 mm Hg. The normal range is 75-100 mm Hg.

3. Recall your knowledge of the function of organelles. What function of the cells was interrupted in these patients?

4. While poison is the main suspect in the case, what are other ways a person could die of hypoxia?

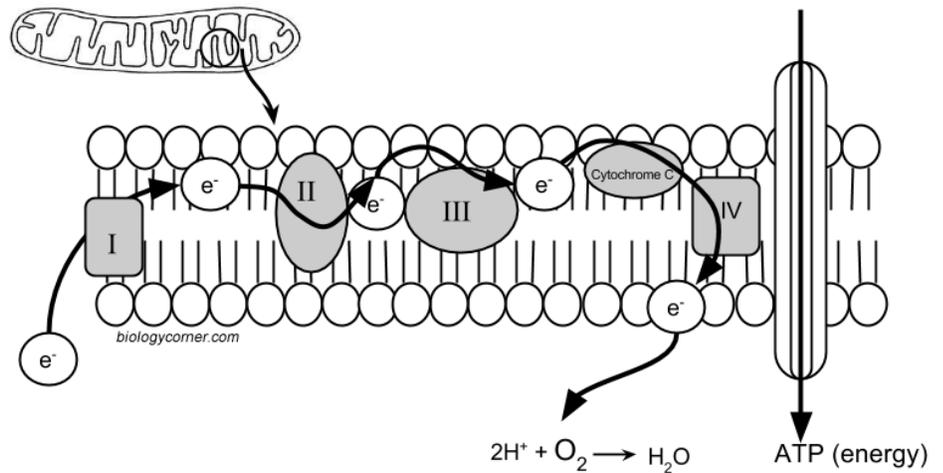

5. Analyze the oxygen levels of the victims. Were the levels higher or lower than normal? How can you reconcile this observation with the cause of death being hypoxia?

Toxicology reports show that the victims had been poisoned with cyanide. The poison was traced back to extra strength Tylenol where the murderer had opened the capsules and replaced acetaminophen (a pain killer) with cyanide. Cyanide acts very quickly, often killing within minutes of ingestion and authorities were slow to identify the cause of the deaths. Once the cause was identified, stores removed Tylenol and other drugs from shelves. While there were many suspects, no one was ever charged with the crime and it is still an ongoing investigation. Since the Chicago Tylenol murders, drug companies have drastically changed how medicines are packaged. Why is cyanide such an effective poison? You might be surprised to learn that it directly interferes with cellular respiration that occurs in the mitochondria.

6. Recall that the mitochondrion is sometimes called the "powerhouse" of the cell. What does this mean? Why is the mitochondrion important?

Part 3: Why Do We Need Oxygen?

It seems like a simple question, everyone knows you need to breathe to live. Have you ever thought about why oxygen is so important? The victims of the cyanide poisoning all had high levels of oxygen in their blood, but the poison was interfering with how the cells use that oxygen. To understand, we need to take a very close look at the structure of the mitochondrion.

Inside the mitochondrion, there are several layers of membranes. In fact, these membranes resemble the membrane that surrounds the cell. It has a bilayer of phospholipids and **embedded proteins**. These proteins, among other things, help the cell move molecules into and out of the cell, or organelle during a process. On the diagram above, the proteins are labeled I, II, III, IV, and Cytochrome C.

The proteins in the membrane pass electrons from one to the other, this is known as the **electron transport chain (ETC)**. It is kind of like a game of hop-scotch. The passing of these electrons allows **ATP** (adenosine triphosphate) to be made. At the end of the electron transport chain, Cytochrome C passes the electron to its final acceptor, oxygen. Oxygen then binds with protons to create water. This process is continuous in cells, with ATP constantly being generated and oxygen being used as the final electron acceptor.

Cyanide inhibits cytochrome C, preventing the last protein, from doing its job. The electron stops at the end of the chain and cannot be passed to oxygen. The whole chain grinds to a halt and no ATP can be made because the oxygen is not taken away in the form of water, like the worst traffic back-up you can imagine.

7. On the model of mitochondrion, **highlight the area (the arrows)** that is the ELECTRON TRANSPORT CHAIN in yellow.

Place an X over the protein that is **inhibited** by cyanide.

Color the phospholipid bilayer (aka cell membrane) blue.

A special protein called ATP synthase generates ATP. Find it on the diagram and **color it red**.

8. What is the relationship between the ETC and oxygen and the phospholipid bilayer (aka cell membrane)?

9. Cyanide is an extremely fast acting poison. In fact, it was developed as a suicide pill (called L-pill) during World War II so that British and American spies could avoid being captured alive. Given what you know about ATP and cellular respiration, explain why cyanide is so fast acting.

10. Given what you know about cyanide poisoning, do you think that giving a person oxygen would be an effective treatment? Why or why not?

11. In biology, cells need to keep all processes and molecules in balance, a concept referred to as homeostasis. Sometimes molecules being able to cross the cell membrane during these processes is crucial to keep cells in a balanced state. How did cyanide change the homeostasis of the cells of a person exposed to it?

Final thoughts? How did you like the activity? What questions do you still have?
